Casperson

### The Ideas

Divide and Conquer

Selecting the Pivot

Partitioning

How to Conquer

### Summary

The End

- We know that we **can** sort in  $O(n^2)$  time.
- We know from sub-sequence sum algorithms that if we can split the problem into two half-size problems we win because  $2(n/2)^2 < n^2$ .
- *Partitioning* splits the problem approximately into half.

Casperson

### The Ideas

Divide and Conquer

Selecting the Pivot

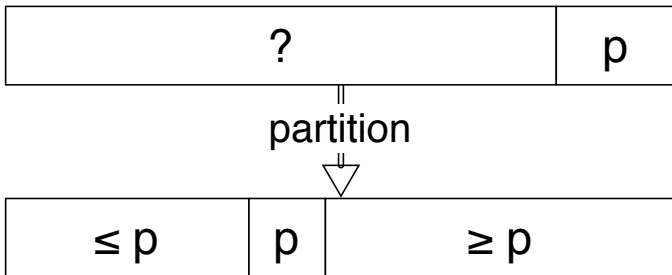

Partitioning

How to Conquer

### Summary

### The End

- The Goal of the Partition algorithm

- The problem with the Partition algorithm ... we don't know how to choose  $p$ .
- Good choices of  $p$  lead to  $\Theta(n \log n)$
- Bad choices lead to  $\Theta(n^2)$ .

# The Partition Algorithm

## Selecting the pivot

- pivot selection is very important
- *Weiss* uses best of three
- the *Weiss* method puts pivots in place
- the *Weiss* method works well with nearly sorted data

### The Ideas

Divide and Conquer

Selecting the Pivot

**Partitioning**

How to Conquer

### Summary

### The End

- elements equal to the pivot are critical  
*swap them to make sure split is equal*
- sentinels are critical  
*let pivot selection put them in place*
- constants are very good
- exploits modern cache well.

# The overall strategy

code

## Quick Sort

### The Ideas

Divide and Conquer

Selecting the Pivot

Partitioning

How to Conquer

### Summary

### The End

```
public static <E>
void qsort_rec(E [] data, int b, int e,
               Comparator<E> c)  {
    if (e-b < cutoff) return ;
    int m = (b+e)/2 ;
    sort3(data, b, m, e-1,  c) ;
    swap(data, m, e-1) ;
    m = partition(data,b,e-1,data[e-1], c) ;
    swap(data, m, e-1) ;
    qsort_rec(data,b,m,c) ;
    qsort_rec(data,m+1,e,c) ;
    return ;
}
```

Need a base case!

# The overall strategy

code

## Quick Sort

David  
Casperson

### The Ideas

Divide and Conquer

Selecting the Pivot

Partitioning

How to Conquer

### Summary

### The End

```
public static <E>
void qsort_rec(E [] data, int b, int e,
               Comparator<E> c)  {
    if (e-b < cutoff) return ;
    int m = (b+e)/2 ;
    sort3(data, b, m, e-1,  c) ;
    swap(data, m, e-1) ;
    m = partition(data,b,e-1,data[e-1], c) ;
    swap(data, m, e-1) ;
    qsort_rec(data,b,m,c) ;
    qsort_rec(data,m+1,e,c) ;
    return ;
}
```

Pick a pivot and move it out of the way.

# The overall strategy

code

## Quick Sort
